# Storage Tier

Mendel Rosenblum

### Web Application Architecture

### Web App Storage System Properties

- Always available Fetch correct app data, store updates
  - Even if many request come in concurrently Scalable
    - From all over the world
  - Even if pieces fail Reliable / fault tolerant
- Provide a good organization of storing an application data
  - Quickly generate the model data of a view
  - Handle app evolving over time
- Good software engineering: Easy to use and reason about

### Relational Database System

- Early on many different structures file system, objects, networks, etc.
  - The database community decided the answer was the **relational** model
    - Many in the community still think it is.
- Data is organized as a series of tables (also called relations)

A table is made of up of **rows** (also called **tuples** or **records**)

A row is made of a fixed (per table) set of typed **columns** 

- String: VARCHAR(20)
- Integer: INTEGER
- Floating-point: FLOAT, DOUBLE
- Date/time: DATE, TIME, DATETIME
- Others

#### **Database Schema**

Schema: The structure of the database

- The table names (e.g. User, Photo, Comments)
- The names and types of table columns
- Various optional additional information (constraints, etc.)

### Example: User Table

### Column types

ID - INTEGER

first\_name - VARCHAR(20)

last\_name - VARCHAR(20)

location - VARCHAR(20)

ID	first_name	last_name	location
1	lan	Malcolm	Austin, TX
2	Ellen	Ripley	Nostromo
3	Peregrin	Took	Gondor
4	Rey	Kenobi	D'Qar
5	April	Ludgate	Awnee, IN
6	John	Ousterhout	Stanford, CA

## Structured Query Language (SQL)

- Standard for accessing relational data
  - Sweet theory behind it: relational algebra
- Queries: the strength of relational databases
  - Lots of ways to extract information
  - You specify what you want
  - The database system figures out how to get it efficiently
  - Refer to data by contents, not just name

## SQL Example Commands

```
DELETE FROM Users WHERE
CREATE TABLE Users (
                                                 last_name='Malcolm';
    id INT AUTO INCREMENT,
    first name VARCHAR(20),
                                              UPDATE Users
    last name VARCHAR(20),
                                                  SET location = 'New York, NY
    location VARCHAR(20));
                                                  WHERE id = 2;
INSERT INTO Users (
                                              SELECT * FROM Users;
   first name,
   last name,
                                              SELECT * from Users WHERE id = 2;
   location)
   VALUES
   ('Ian',
   'Malcolm',
    'Austin, TX');
                                CS142 Lecture Notes - Database
```

### Keys and Indexes

Consider a model fetch: SELECT \* FROM Users WHERE id = 2

Database could implement this by:

- 1. **Scan** the Users table and return all rows with id=2
- 2. Have built an **index** that maps id numbers to table rows. Lookup result from index.

Uses keys to tell database that building an index would be a good idea

Primary key: Organize data around accesses

PRIMARY KEY(id) on a CREATE table command

Secondary key: Other indexes (UNIQUE)

CS142 Lecture Notes - Database

### Object Relational Mapping (ORM)

- Relational model and SQL was a bad match for Web Applications
  - Object versus tables
  - Need to evolve quickly
- 2<sup>nd</sup> generation web frameworks (Rails) handled mapping objects to SQL DB
- Rail's Active Record
  - Objects map to database records
  - One class for each table in the database (called Models in Rails)
  - Objects of the class correspond to rows in the table
  - Attributes of an object correspond to columns from the row
- Handled all the schema creation and SQL commands behind object interface

### NoSQL - MongoDB

- Using SQL databases provided reliable storage for early web applications
- Led to new databases that matched web application object model
  - Known collectively as NoSQL databases
- MongoDB Most prominent NoSQL database
  - Data model: Stores collections containing documents (JSON objects)
  - Has expressive query language
  - Can use indexes for fast lookups
  - Tries to handle scalability, reliability, etc.

#### Schema enforcement

- JSON blobs provide super flexibility but not what is always wanted
  - o Consider: <h1>Hello {{person.informalName}}</h1>
    - Good: typeof person.informalName == 'string' and length < something
    - Bad: Type is 1GB object, or undefined, or null, or ...
- Would like to enforce a schema on the data
  - Can be implemented as validators on mutating operations
- Mongoose Object Definition Language (ODL) not doing relational map
  - Take familiar usage from ORMs and map it onto MongoDB
  - Effectively masks the lower level interface to MongoDB with something that is friendlier

## Using: var mongoose = require('mongoose');

1. Connect to the MongoDB instance

```
mongoose.connect('mongodb://localhost/cs142');
```

2. Wait for connection to complete: Mongoose exports an EventEmitter

```
mongoose.connection.on('open', function () {
    // Can start processing model fetch requests
});
```

mongoose.connection.on('error', function (err) { });

Can also listen for connecting, connected, disconnecting, disconnected, etc.

### Mongoose: Schema define collections

Schema assign property names and their types to collections

```
String, Number, Date, Buffer, Boolean
Array - e.g. comments: [ObjectId]
ObjectId - Reference to another object
Mixed - Anything
  var userSchema = new mongoose.Schema({
      first name: String,
      last name: String,
      emailAddresses: [String],
      location: String
  });
                         CS142 Lecture Notes - Database
```

### Schema allows secondary indexes and defaults

Simple index

```
first_name: {type: 'String', index: true}
```

Index with unique enforcement

```
user_name: {type: 'String', index: {unique: true} }
```

Defaults

```
date: {type: Date, default: Date.now }
```

### Secondary indexes

- Performance and space trade-off
  - Faster queries: Eliminate scans database just returns the matches from the index
  - Slower mutating operations: Add, delete, update must update indexes
  - Uses more space: Need to store indexes and indexes can get bigger than the data itself

#### When to use

- Common queries spending a lot of time scanning
- Need to enforce uniqueness

### Mongoose: Make Model from Schema

 A Model in Mongoose is a constructor of objects a collection May or may not correspond to a model of the MVC

```
var User = mongoose.model('User', userSchema);
```

Create objects from Model

```
User.create({ first_name: 'Ian', last_name: 'Malcolm'}, doneCallback);
function doneCallback(err, newUser) {
   assert (!err);
   console.log('Created object with ID', newUser._id);
}
```

### Model used for querying collection

Returning the entire User collection

```
User.find(function (err, users) {/*users is an array of objects*/ });
```

Returning a single user object for user\_id

```
User.findOne({_id: user_id}, function (err, user) { /* ... */ });
```

Updating a user object for user\_id

```
User.findOne({_id: user_id}, function (err, user) {
    // Update user object - (Note: Object is "special")
    user.save();
});

CS142 Lecture Notes - Database
```

## Other Mongoose query operations - query builder

```
var query = User.find({}); no call back, does not run
  Projections
   query.select("first name last name").exec(doneCallback);
Sorting
   query.sort("first name").exec(doneCallback);
   Limits
   query.limit(50).exec(doneCallback);
query.sort("-location").select("first name").exec(doneCallback);
```

### Deleting objects from collection

Deleting a single user with id user\_id

```
User.remove({_id: user_id}, function (err) { } );
```

Deleting all the User objects

```
User.remove({}, function (err) { } );
```
